

Is Alzheimer's disease-glioblastoma transcriptomic overlap real, or cell composition and age?

Bulk tissue (H1)

Shared AD-GBM DEGs, before and after adjustment for estimated cell composition

Cell-type level (H2)

No overlap detected with the available donors
(3 pre-specified tests; 3 donors per group)

Apparent convergence signal

RRHO2 signal (−log10 P); age and Braak stage
did not overlap in the discovery cohort

Shared bulk signatures track estimated cell composition; cross-disease comparisons need composition adjustment, donor-level inference and attention to age.
